A typical hard disk drive includes one or more platters or disks, each platter including a magnetic storage medium. Each platter is divided into a series of concentric tracks. Read/write heads are moved radially across the tracks to read data from or write data to the platter surfaces. In a typical hard disk drive, the head (or heads) are mounted on an actuator arm which is moved across the platters by a positioning motor. The platters are rotated by a spindle motor which is controlled by a servo control system. The servo control system controls the positioning of the actuator arm so that the read/write heads are able to read from or write to a selected track on the disk platter. In a typical hard disk drive, the servo control system includes a disk controller coupled to a microprocessor or controller. The microprocessor or controller controls the operation of the disk drive by executing instructions stored in a read-only memory. The microprocessor or controller also transfers data to and from the hard disk drive and controls the operation of the spindle motor and positioning motor. Modern hard disk drives increasingly employ magnetoresistive (MR) heads instead of the traditional inductive heads. The MR head is designed to read data from the magnetic platter surfaces. The magnetic platter surfaces of the hard disk platters are made from a magnetic material, such as Permalloy, having a high coercivity. A write transducer is used to magnetize the platters in a manner that represents data. During a read operation, a read transducer can retrieve data from the magnetic platter surface. Referring to FIG. 1, one type of hard disk drive, known as a "rotary" drive, employs a read/write head or transducer 10 mounted on an actuator arm 12 that is rotated by a motor 14. The actuator arm 12 is pivoted by a voice-coil motor (VCM) 16 about a bearing 18. A magnet 20 is mounted on a portion of the actuator arm 12, and a read/write head 10, for
