The quantitative microbiological analysis of foods and related materials is a well established art. Such analysis is especially important in the dairy industry, where the products are likely to be contaminated with a broad spectrum of microorganisms, including bacteria, molds, yeasts, and other microorganisms. One common method of analysis, whether for the dairy industry or otherwise, is the quantitative plate count method. A typical method includes the steps of: (1) incubating a small quantity of a sample on a nutrient-rich medium in Petri dishes; (2) incubating the medium until colonies of microorganisms are observed; (3) removing the colonies from the medium; (4) counting the colonies; and (5) multiplying the count by a known factor to determine the number of microorganisms per ml or other unit volume of the sample. The known factors may be entered into a computerized system, which may then be used to perform a series of calculations and yield an average value for the sample. A number of published U.S. patents, including for example, U.S. Pat. No. 3,815,960, are based on this method of analysis. An alternative to the plate count method is the flow-through method, in which the sample and a culture medium are passed through a column or channel of a membrane or other filter. The microorganisms and the culture medium flow through the column or channel and cannot pass through the filter. The microorganisms adhere to the filter, which has a specified pore size. The microorganisms can then be counted manually or by a filter-reading instrument. The above described methods are accurate when microorganisms are evenly distributed throughout the sample. As a practical matter, however, the number of

microorganisms in a sample is often not even or uniform, and as a result, either the number of microorganisms per ml or the number of microorganisms per gram of the sample cannot be determined precisely. It is therefore an object of the present invention to provide a method of determining the number of microorganisms in a sample, such as a food or feed sample, which method is more reliable than prior methods. 6 2 * d 2d92ce491b
