Modern authentication is based on several symmetric key algorithms that were designed to ensure that data is properly encoded. Encryption is the process of transforming data into a form that is not understandable by anyone but the intended recipient. A hash is a one-way method that is used to create a digital fingerprint for a file or an object, making it impossible to derive the original data. Authocation is the process of generating an encrypted file that is authenticated by the sender. In the majority of cases, authentication is not equal to encryption, because it is not intended to be a backup of the information. Using a MAC is the process of encrypting the information to ensure that the file is not modified and that it cannot be tampered with by others. The purpose of creating a hash is to verify that the information has not been modified, by using a one-way process. Public-key cryptography is the process of dividing keys into two types. A public key is used to encrypt data, while a private key is used to decrypt it. In short, this is a method of verifying the authenticity of a file, by using a private key to decipher an encrypted message. Key generation is a process that is used to create two keys, which are used to encode or decode data. Keys are essentially the same as passwords, and they can be used to encrypt data. To summarise, the tool offers you a variety of powerful and reliable authentication algorithms that are not only user-friendly, but also easy to use and implement. Supported encryption algorithms: XOR DES RC4 AES CAST GOST Blowfish SHA MD5 HMAC CRC Public-key cryptography: RSA DSA ECDSA User-friendly interface: YES Key generation: YES Inventory: YES Hash generation: YES Message Authentication Code: YES Key confirmation: YES Conclusion Keymacro is a powerful and reliable data encoder, which is easy to use and implement. It can generate public and private keys, as well as hash codes and message authentication codes, using a variety of encryption algorithms.
