A family of gene fragments, each containing at least two sequences of at least 50% identical nucleotides, was isolated from a rat brain library. Only two of these clones were homologous with sequences in any known gene. Further analysis showed that the sequences highly homologous to kinases that we have isolated from the mouse brain library (mict1a) were different from those already reported (ryanodine receptor and calcium channel). The second clone, mict2b, showed a very high homology of 66% at the nucleotide level, but a much lower similarity (20%) of the translated amino acid sequence with all known protein kinases. The data indicate that the mict1a and mict2b genes encode nuclear proteins with sequences similar to those of kinases and that they represent new members of the protein kinase family.In the art of electrostatographic printing, the image to be printed is typically formed by attracting toner to a charged surface by means of an applied electric field. An exemplary form of the imaging process is described in Carlson's U.S. Pat. No. 2,297,691 issued Oct. 6, 1942. In this process, the image is formed by charging the surface of a photoconductive insulating layer affixed to a carrier and exposing the charged surface to light and shadow images to selectively dissipate the charge on the illuminated areas of the photoconductive insulating layer while leaving behind a latent electrostatic image on the non-illuminated areas. The latent electrostatic image is subsequently developed into a toner image by depositing finely divided pigmented particles of a resinous substance called toner on the electrostatic image. The toner image is normally transferred from the photoconductive 3da54e8ca3
