reaching a given antimatter beam can go? It is said that antimatter can reach a max distance of just under a light year, given ideal conditions. But I have also heard that if it reaches the surface of the Sun, it will instantly be annihilated. This seems highly unlikely. Why is this? What would happen if an antimatter beam were to reach the surface of the Sun? What does the Sun do to it? A: I don't think that the sun will instantly destroy antimatter beams which reaches it, but it will annihilate it, a bit like the "antigravity", basically the main engine of the beam will be self-evident. The star only absorbs the momentum of the beam. The energies and the mass will be absorbed by the star. But the antimatter beam will be turned into a neutrino beam, which is a visible radiation. The amount of energy that is absorbed will make a sphere around the star. Antimatter particle reaction with normal matter is a highly exothermic chemical reaction. An antimatter particle and a normal particle of similar energy will emit a high-energy gamma ray, a high energy neutrino,
